

Mineral Carbonation Processes for Recycled Concrete Aggregate

Johannes Tiefenthaler and Marco Mazzotti
TCCS10, Trondheim

ETH Zurich, Switzerland

Outline

- 1) Background and motivation
- 2) System integration aspects
- 3) Experimental proof of concept

Concrete manufacturing and recycling landscape

Carbonation of concrete

- limits life time of concrete structure
- stores CO_2
- densifies the material

Physics behind carbonation of concrete

Carbonation of concrete – state of the art

Modelling

Mass balance over CO_2 , $\text{Ca}(\text{OH})_2$, CSH, C_3S , C_2S

Figure 4. Slab and control volume geometry.

Diffusion with reaction

$$\frac{\partial c_{\text{CO}_2}}{\partial t} = \frac{\partial}{\partial x} \left(D_{\text{CO}_2} \frac{\partial c_{\text{CO}_2}}{\partial x} \right) - r_{\text{CaCO}_3}$$

Carbonation depth

$$x_c = \sqrt{\frac{2p_{\text{CO}_2} D_{\text{CO}_2} t}{c_{\text{Ca}(\text{OH})_2}^0 + c_{\text{CSH}}^0}}$$

Model validation

Natural carbonation

indoor exposure

Accelerated carbonation

20% CO_2 / 52% RH / 20°C / W/C 0.4 - 0.6

Carbonation of concrete – state of the art

Modelling

Mass balance over CO_2 , $\text{Ca}(\text{OH})_2$, CSH, C_3S , C_2S

Figure 4. Slab and control volume geometry.

Diffusion with reaction

$$\frac{\partial c_{\text{CO}_2}}{\partial t} = \frac{\partial}{\partial x} \left(D_{\text{CO}_2} \frac{\partial c_{\text{CO}_2}}{\partial x} \right) - r_{\text{CaCO}_3}$$

Carbonation depth

$$x_c = \sqrt{\frac{2p_{\text{CO}_2} D_{\text{CO}_2} t}{c_{\text{Ca}(\text{OH})_2}^0 + c_{\text{CSH}}^0}}$$

Effect of relative humidity

50% CO_2 / 30°C / W/C 0.65 / 5 days

Kelvin radius

$$r = -\ln \left(\frac{p_v}{p_{\text{sat}}} \right)^{-1} \gamma \frac{V_l}{RT}$$

Capillary condensation

Outline

- 1) Background and motivation
- 2) System integration aspects
- 3) Experimental proof of concept

Objective and outline

Global CO₂ uptake potentials for direct mineral carbonation processes

Round numbers:

- Nominal CO₂ uptake capacity of concrete: 150 kg CO₂ / m³
- Technical potential for direct carbonation processes: 100 kg CO₂ / m³
- Natural carbonation: 10 kg CO₂ / m³
- Global amount of demolition concrete: 400 Mm³/y
- Global technical potential: 40 Mt CO₂/y

Outline

- 1) Background and motivation
- 2) System integration aspects
- 3) Experimental proof of concept

Experimental setup – process flow sheet

Feed conditions

$$T = 25^{\circ}\text{C}$$

$$y_{\text{CO}_2} = 25\%$$

$$p_{\text{amb.}} = 0.95 \text{ bar}$$

$$F_{\text{in}} = 3.1 \text{ mmol/min}$$

$$\text{RH}_{\text{in}} = 55 / 60 / 75 \%$$

Properties of packed bed

$$d_p = 4\text{-}16 \text{ mm}$$

$$m_{\text{cem}} = 400 \text{ g}$$

$$n_{\text{CO}_2}^{\text{max}} = 0.38 \text{ mol (on a base of } 100 \text{ kg CO}_2/\text{m}^3\text{)}$$

Initial conditions

$$y_{\text{CO}_2} = 0\%$$

$$y_{\text{N}_2} = 100\%$$

$$\text{RH} = 55 / 60 / 75 \%$$

Experimental proof of concept I

[mol]

RH 55

**Observations I:**

1. The gas outlet stream gets humidified throughout the carbonation process
2. The CO₂ outlet concentration profile has 3 phases.

Experimental proof of concept I

[mol]	RH 55	RH 60	RH 75
$n_{\text{CO}_2}^{\text{in}} - n_{\text{CO}_2}^{\text{out}}$	0.16 (38%)		
$n_{\text{H}_2\text{O}}^{\text{out}} - n_{\text{H}_2\text{O}}^{\text{in}}$	0.023		

Observations II:

1. At lower RH, significantly more CO_2 can be stored within the experimental time.
2. The RH of the outlet gas flow seems to be controlled by the evaporation of the water formed throughout the carbonation.

Conclusions

- We advocate the use of demolition concrete as a way to store CO₂ permanently, since:
 - carbonation processes can be integrated with current concrete recycling practices.
 - 40 Mt CO₂/y can be stored.
- Experiments showed that within 12 hours, demolition concrete of common particle size can store 30 kg CO₂ / m³, corresponding to 1/3 of its technical storage capacity.
- These preliminary tests confirm that lower relative humidities enhance the CO₂ uptake of demolition concrete.
